

(1) Discuss communicable diseases under the following headings.

Definition

Communicable diseases are caused by infectious agents that can spread through various routes, including direct contact, airborne transmission, contaminated food and water, or vector-borne transmission.

Causative Agents

1. Bacteria : _Streptococcus pneumoniae_ (pneumonia), _Mycobacterium tuberculosis_ (tuberculosis).
2. Viruses : Influenza virus (influenza), HIV (AIDS), SARS-CoV-2 (COVID-19).
3. Fungi : _Candida albicans_ (candidiasis).
4. Parasites : _Plasmodium_ spp. (malaria), Entamoeba histolytica_ (amoebiasis).

Modes of Transmission

1. Direct Contact : Touching, kissing, or sexual contact.
2. Airborne Transmission : Inhaling droplets or aerosols containing pathogens.
3. Contaminated Food and Water : Consuming food or water contaminated with pathogens.
4. Vector-Borne : Transmitted through bites from infected insects (e.g., mosquitoes, ticks).
5. Fomite Transmission : Touching contaminated surfaces or objects.

Methods of Prevention and Control

1. Vaccination : Immunization against specific diseases (e.g., measles, polio).
2. Hygiene Practices : Handwashing, covering mouth and nose when coughing or sneezing.
3. Safe Food and Water : Proper food handling, cooking, and water treatment.
4. Vector Control : Using insect repellents, bed nets, and eliminating breeding sites for vectors.
5. Isolation and Quarantine : Isolating infected individuals and quarantining exposed individuals.
6. Public Health Measures : Implementing policies and programs to control outbreaks and prevent transmission.

(2) Explain the terms endemic, epidemic and pandemic, giving examples

Endemic

An **endemic** disease is a disease that is consistently present and prevalent within a specific geographic area or population. It can be at a relatively low or stable rate, but it is always present.

Examples

- Malaria in certain parts of Africa.
- Dengue fever in tropical regions.

Epidemic

An **epidemic** occurs when the number of cases of a disease significantly increases beyond what is normally expected within a specific area or population over a particular period. Epidemics are often sudden and can be contained with public health interventions.

Examples

- Cholera outbreaks in areas with poor sanitation.
- Influenza outbreaks in schools or nursing homes.

Pandemic

A **pandemic** is a global outbreak of a disease that spreads across multiple countries or continents, affecting a large number of people. Pandemics are often caused by highly infectious diseases that can spread rapidly.

Examples

- COVID-19 pandemic (2019-2023).
- Spanish flu pandemic (1918-1919)

(3) Define and distinguish between incidence and prevalence. Explain their importance in epidemiology with examples.

Incidence

Incidence refers to the number of **new cases** of a disease or condition that occur within a specified period among a population at risk. It measures the rate at which new cases develop.

Examples

If 10 new cases of malaria are diagnosed in a town of 1,000 people over a year, the incidence rate is 10 cases per 1,000 people per year.

Prevalence

Prevalence refers to the ***total number of cases*** (new and existing) of a disease or condition in a population at a specific point in time or over a period. It measures the proportion of the population affected.

Example

If 50 people in a town of 1,000 have diabetes, the prevalence is 5%.

Importance in Epidemiology

1. Understanding Disease Burden : Prevalence helps assess the overall impact of a disease on a population.
2. Tracking Disease Trends : Incidence helps identify new outbreaks or changes in disease patterns.
3. Resource Allocation : Both measures guide public health planning and resource distribution.
4. Evaluating Interventions : Changes in incidence and prevalence can indicate the effectiveness of public health interventions.

Examples

- ***Incidence***: Tracking the number of new COVID-19 cases each week to monitor the spread of the virus.
- ***Prevalence***: Measuring the total number of people living with HIV/AIDS in a region to allocate resources for treatment and care

(4) Describe the measures used in controlling communicable diseases at the community level.

1. Vaccination Programs

Vaccination is one of the most effective ways to prevent the spread of communicable diseases. Community-wide vaccination campaigns can build herd immunity, reducing transmission and protecting vulnerable populations.

2. Hygiene Practices

Promoting good hygiene practices, such as regular hand washing with soap, using hand sanitizers, and proper waste disposal, can significantly reduce the transmission of infectious diseases.

3. Access to Clean Water and Sanitation

Ensuring access to clean water for drinking, cooking, and sanitation is crucial in preventing

waterborne diseases. Improving sanitation facilities and promoting proper hygiene practices can also reduce the spread of diseases.

4. Disease Surveillance and Early Detection

Establishing surveillance systems to track disease trends and detect outbreaks early enables prompt intervention, contact tracing, and effective outbreak response.

5. Public Awareness and Education

Educating the community about communicable diseases, their transmission, prevention measures, and the importance of seeking medical help early can empower individuals to protect themselves and others.

6. Social Distancing Measures

Implementing social distancing measures, such as isolation and quarantine, can help reduce the spread of diseases. This can include closing public venues, canceling public events, and promoting remote work.

7. Community Engagement

Engaging with the community and involving them in disease control efforts can improve the effectiveness of interventions. This can include working with community leaders, mobilizing community volunteers, and promoting participatory learning and action cycles

8. Vector Control

Implementing vector control measures, such as eliminating breeding sites for mosquitoes and other vectors, can help reduce the spread of vector-borne diseases like malaria and dengue fever

(5) Write short notes on the following:

- a. Epidemiological triangle
- b. Vehicle-borne transmission
- c. Point prevalence and period prevalence

(A) Epidemiological Triangle

The *epidemiological triangle* (also known as the epidemiologic triad) is a model that explains the interaction between:

1. *Host* (human or animal)
2. *Agent* (pathogen or cause)

3. *Environment* (external factors)

(B) Vehicle-borne Transmission

Vehicle-borne transmission occurs when a pathogen is transmitted through a contaminated medium, such as:

1. Water (e.g., cholera)
2. Food (e.g., salmonella)
3. Blood (e.g., HIV)
4. Air (e.g., Legionella in air conditioning systems)

(C) Point Prevalence and Period Prevalence

- *Point Prevalence*: The total number of cases (new and existing) of a disease in a population at a *specific point in time*.

- *Period Prevalence*: The total number of cases of a disease in a population over a *specified period* (e.g., a month, year).
